Acknowledgments

The author would like to thank Mr. Richard Pearson and Dr. Benjamin Breech of the U.S. Army Research Laboratory's Weapons and Materials Research Directorate. Mr. Pearson's many technical and editorial recommendations improved the quality of this report. Dr. Breech's advice on C++ improved the code contained in this report.

1. Introduction

This report represents the first of two reports, each of which documents a portion of a larger project. The ultimate goal of the project is to produce an end-to-end smart-trajectory model.

Presented in this report is the development of a plant (*I*) model that is based on the equations of motion of a maneuvering projectile. Control forces and rocket propulsion, as well as gravity, drag, and Coriolis forces, have been incorporated into the model. The purpose of the model is twofold—first, it will be used to predict future states of a projectile in order to fine-tune in-flight guidance parameters, and second, it will be the basis of an extended Kalman filter that will be used to improve upon the accuracy of the measured state of a projectile. Also included in this report is a C++ implementation of the model. The C++ implementation has been written in a matter that will both allow it to be incorporated into an extended Kalman filter and be compatible with a larger smart-trajectory model that can be run in parallel on a high-performance computing platform.

A future report (the second of this pair) will contain the details of an extended Kalman filter, along with a simple sensor model and a pair of algorithms that will be useful for optimizing control parameters.

2. Coordinate Systems

Three distinct coordinate systems are used for this model. A geographic coordinate system is used to locate the origin of a topocentric coordinate system with respect to a location on the surface of the earth, a topocentric coordinate system is used to track the position of a projectile as it moves through space, and a projectile-fixed coordinate system is used to orient control forces.

2.1 Geographic Coordinates

Both the atmospheric model and the Coriolis force equations that are included in this model are sensitive to variations in latitude and altitude. As a result, a geographic coordinate system is used to locate the starting location of a projectile with respect to the surface of the earth.

Due to assumed symmetry of the earth about its axis of rotation, this model is independent of longitude. Furthermore, changes in elevation are accounted for in the topocentric coordinate system, so elevation in the geographic coordinate system is fixed at sea level. Thus, although three coordinates are needed to fully specify a position in geographic coordinates, for this model, only latitude (Θ) is treated as a variable. Figure 1 shows how the geographic coordinate system is used to define the origin of the topocentric coordinate system with respect to the surface of the earth.

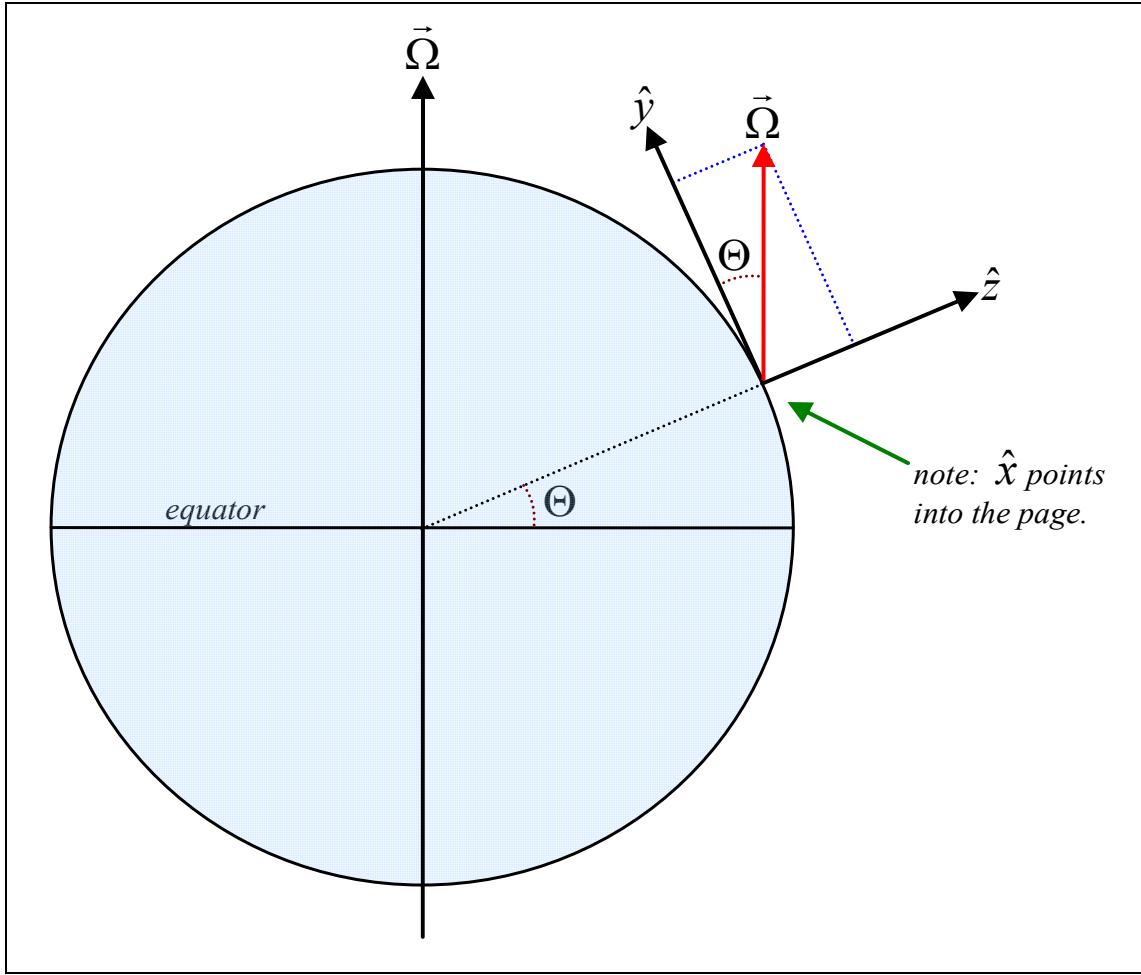

Figure 1. Relationship between geographic and topocentric coordinate systems.

2.2 Topocentric Coordinates

The equations of motion for this model are given in Cartesian, topocentric coordinates. The variables x , y , and z are used to specify a point in space in the topocentric coordinate system. Specifically, \hat{x} is defined to point east, \hat{y} is defined to point north, and \hat{z} is defined to point in the direction of the local vertical.

Note that since the topocentric coordinate system is Cartesian, the x - y plane does not conform to the surface of the earth. A result of this is that the only locations where \hat{x} , \hat{y} , and \hat{z} point *exactly* east, north, and up are along the z axis. Everywhere else, \hat{x} , \hat{y} , and \hat{z} point *approximately* east, north, and up.

2.3 Projectile-Fixed Coordinates

The directions of the control forces that are included in this model are determined by a projectile's direction of travel. Thus, a projectile-fixed coordinate system is used to orient the control forces. Figure 2 shows the relationship between the projectile-fixed coordinate system and the topocentric coordinate system.

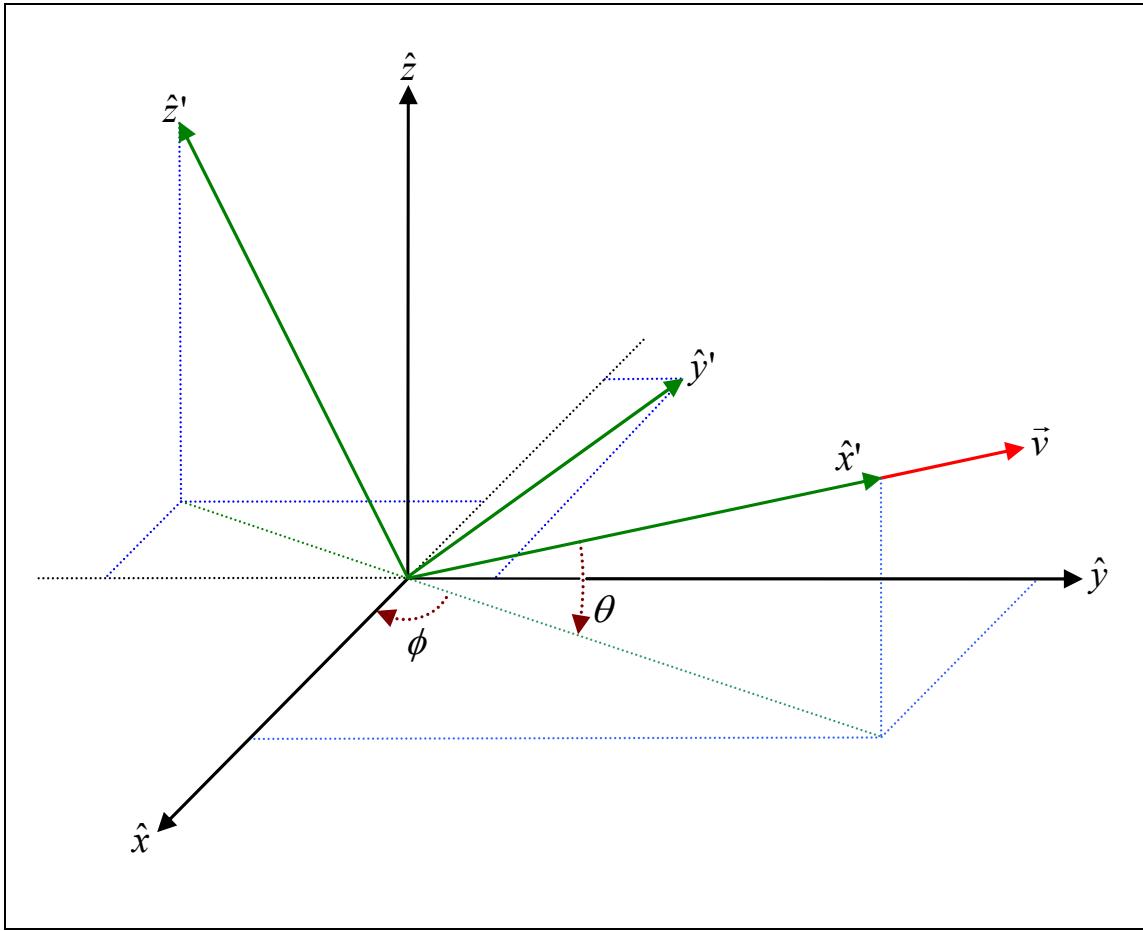

Figure 2. Relationship between topocentric and projectile-fixed coordinate systems.

The variables x' , y' , and z' are used to specify a point in space in the projectile-fixed coordinate system. Specifically, \hat{x}' is defined to be aligned with a projectile's velocity vector (\vec{v}), \hat{y}' is defined to point to the left of a projectile's velocity vector, and \hat{z}' is defined to satisfy normal right-hand-rule conventions. In equation form, \hat{x}' , \hat{y}' , and \hat{z}' are defined as follows:

$$\hat{x}' = \frac{\vec{v}}{|\vec{v}|}, \quad (1)$$

$$\hat{y}' = \frac{\hat{z} \times \vec{v}}{|\hat{z} \times \vec{v}|}, \quad (2)$$

and

$$\hat{z}' = \frac{\hat{x}' \times \hat{y}'}{|\hat{x}' \times \hat{y}'|}. \quad (3)$$

3. Coordinate Conversions

3.1 Topocentric to Geographic

Conversion from topocentric coordinates to geographic coordinates should be through an inverse azimuthal equidistant projection. Doing so will accurately preserve both distance from the origin and direction in the x - y plane. The C++ library GeographicLib (2) contains a function that will perform an inverse azimuthal equidistant projection.

3.2 Geographic to Topocentric

Conversion from geographic coordinates to topocentric coordinates should be through an azimuthal equidistant projection. Doing so will accurately preserve both distance from the origin and direction in the x - y plane. The C++ library GeographicLib (2) contains a function that will perform an azimuthal equidistant projection.

3.3 Projectile-Fixed to Topocentric

A vector given in terms of projectile-fixed coordinates can be converted to topocentric coordinates through a pair of rotations. This can be accomplished by first rotating about the y' axis through an angle of θ and then rotating about the new z' axis through an angle of ϕ .

Rotation matrices can be used to perform the desired rotations. Those matrices are presented in equations 4 and 5, where A_y is a counterclockwise rotation about the y' axis by an angle of α and $A_{z'}$ is a counterclockwise rotation about the new z' axis by an angle of β (3).

$$A_{y'} = \begin{bmatrix} \cos \alpha & 0 & -\sin \alpha \\ 0 & 1 & 0 \\ \sin \alpha & 0 & \cos \alpha \end{bmatrix}, \quad (4)$$

and

$$A_{z''} = \begin{bmatrix} \cos \beta & \sin \beta & 0 \\ -\sin \beta & \cos \beta & 0 \\ 0 & 0 & 1 \end{bmatrix}. \quad (5)$$

Referring to figure 2, note that θ represents a counterclockwise rotation, while ϕ represents a clockwise rotation. Thus,

$$\alpha = \theta, \quad (6)$$

and

$$\beta = -\phi. \quad (7)$$

Substituting equations 6 and 7 into equations 4 and 5 produces rotation matrices in terms of θ and ϕ .

$$A_{y'} = \begin{bmatrix} \cos \theta & 0 & -\sin \theta \\ 0 & 1 & 0 \\ \sin \theta & 0 & \cos \theta \end{bmatrix}, \quad (8)$$

and

$$A_{z''} = \begin{bmatrix} \cos \phi & -\sin \phi & 0 \\ \sin \phi & \cos \phi & 0 \\ 0 & 0 & 1 \end{bmatrix}. \quad (9)$$

Note that in order to correctly apply the rotation matrices, they must be used in the proper order. This can be somewhat counterintuitive. Consider a generic vector \vec{B}' that is defined in terms of the projectile-fixed coordinate system. Since $A_{y'}$ acts on \vec{B}' first, it is placed immediately to the left of \vec{B}' . $A_{z''}$ acts on the product of $A_{y'}$ and \vec{B}' , so $A_{z''}$ is placed to the left of $A_{y'}$. Thus,

$$\vec{B} = A_{z''} A_{y'} \vec{B}'. \quad (10)$$

Equation 11 shows the product of the two rotation matrices.

$$A_{z''} A_{y'} = \begin{bmatrix} \cos \phi \cos \theta & -\sin \phi & -\cos \phi \sin \theta \\ \sin \phi \cos \theta & \cos \phi & -\sin \phi \sin \theta \\ \sin \theta & 0 & \cos \theta \end{bmatrix}. \quad (11)$$

It will be helpful to convert the right side of equation 11 into a matrix comprised of velocity components rather than sines and cosines. Trigonometric identities can be used, along with figure 2, to represent $\sin \theta$, $\cos \theta$, $\sin \phi$, and $\cos \phi$ in terms of v , v_x , v_y , and v_z . Also, the introduction of the unitless variable γ will simplify several of the derived relationships.

$$\gamma = \frac{1}{\sqrt{1 - \frac{v_z^2}{v^2}}}, \quad (12)$$

$$\sin \theta = \frac{v_z}{v}, \quad (13)$$

$$\cos \theta = \frac{\sqrt{v_x^2 + v_y^2}}{v} = \frac{\sqrt{v^2 - v_z^2}}{v} = \frac{v \sqrt{1 - \frac{v_z^2}{v^2}}}{v} = \frac{1}{\gamma}, \quad (14)$$

$$\sin \phi = \frac{v_y}{\sqrt{v_x^2 + v_y^2}} = \frac{v_y}{\sqrt{v^2 - v_z^2}} = \frac{v_y}{v \sqrt{1 - \frac{v_z^2}{v^2}}} = \frac{\gamma v_y}{v}, \quad (15)$$

and

$$\cos \phi = \frac{v_x}{\sqrt{v_x^2 + v_y^2}} = \frac{\gamma v_x}{v}. \quad (16)$$

Substituting equations 13–16 into equation 11 gives a rotation matrix that is represented in terms of velocity components.

$$A_z A_y = \begin{bmatrix} \frac{v_x}{v} & -\frac{\gamma v_y}{v} & -\frac{\gamma v_x v_z}{v^2} \\ \frac{v_y}{v} & \frac{\gamma v_x}{v} & -\frac{\gamma v_y v_z}{v^2} \\ \frac{v_z}{v} & 0 & \frac{1}{\gamma} \end{bmatrix}. \quad (17)$$

4. Forces Acting on a Projectile

The model described in this report considers seven forces that act on a projectile. These are gravity, thrust, Coriolis, air resistance, and three control forces. Control forces are categorized as either causing a projectile to lift or turn, or as contributing to the overall air resistance of a projectile.

4.1 Gravity

In the topocentric coordinate system, gravity is assumed to always point in the $-\hat{z}$ direction. Thus,

$$\vec{F}_{grav} = m\vec{g} = -mg\hat{z}. \quad (18)$$

The value for g is determined by using the gravitational model specified in the “U.S. Standard Atmosphere” (4).

$$g = g_0 \left(\frac{r_0}{r_0 + z} \right)^2, \quad (19)$$

where r_0 is the effective radius of the earth and g_0 is the value of g at sea level.

4.2 Thrust

It is assumed that the long axis of a projectile always points in the same direction as the projectile's velocity vector. As a result, the force due to thrust points in the same direction as the velocity vector. Thus,

$$\vec{F}_{\text{thrust}} = T\hat{v} = T \frac{\vec{v}}{v}, \quad (20)$$

where T is the magnitude of the thrust force and is typically given as a piecewise function of time.

Note that the velocity vector can be generically broken into its components in the topocentric coordinate system. Thus,

$$\vec{v} = v_x \hat{x} + v_y \hat{y} + v_z \hat{z}. \quad (21)$$

Substituting equation 21 into equation 20,

$$\vec{F}_{\text{thrust}} = \frac{T v_x}{v} \hat{x} + \frac{T v_y}{v} \hat{y} + \frac{T v_z}{v} \hat{z}. \quad (22)$$

It will be helpful to define a new value whose sole purpose is to simplify equations as follows:

$$\bar{T} \equiv \frac{T}{mv}. \quad (23)$$

Substituting equation 23 into equation 22,

$$\vec{F}_{\text{thrust}} = m\bar{T}v_x \hat{x} + m\bar{T}v_y \hat{y} + m\bar{T}v_z \hat{z}. \quad (24)$$

4.3 Coriolis

The Coriolis force is a pseudo force that comes about as a result of choosing a rotating coordinate system such as the topocentric coordinate system used for this model. It is perpendicular to both the earth's angular-velocity vector ($\vec{\Omega}$) and a projectile's velocity vector (\vec{v}) (5). Specifically,

$$\vec{F}_{\text{Coriolis}} = -2m\vec{\Omega} \times \vec{v}. \quad (25)$$

Referring to figure 1, the earth's angular velocity can be described by equation 26.

$$\vec{\Omega} = \Omega \cos \Theta \hat{y} + \Omega \sin \Theta \hat{z}. \quad (26)$$

Substituting equations 21 and 26 into equation 25 and calculating the cross product,

$$\vec{F}_{\text{Coriolis}} = 2m\Omega(v_y \sin \Theta - v_z \cos \Theta)\hat{x} - 2m\Omega v_x \sin \Theta \hat{y} + 2m\Omega v_x \cos \Theta \hat{z}. \quad (27)$$

4.4 Air Resistance

The force due to air resistance (i.e., drag) points in a direction opposite to the direction of travel and is proportionate to the speed of the projectile squared (6). Specifically,

$$\vec{F}_{\text{drag}} = -\frac{1}{2}\rho A C_D v \vec{v}, \quad (28)$$

where ρ is the density of air at the location of a projectile, A is the cross-sectional area of a projectile, and C_D is a projectile's drag coefficient. Note that air density is calculated by the method described in the "U.S. Standard Atmosphere" (see Yager [7] for a summary of the process.)

Substituting equation 21 into equation 28,

$$\vec{F}_{\text{drag}} = -\frac{1}{2}\rho A C_D v v_x \hat{x} - \frac{1}{2}\rho A C_D v v_y \hat{y} - \frac{1}{2}\rho A C_D v v_z \hat{z}. \quad (29)$$

It will be helpful to define another new value whose sole purpose is to simplify equations:

$$\bar{C} \equiv \frac{1}{2m}\rho A C_D. \quad (30)$$

Substituting equation 30 into equation 29,

$$\vec{F}_{\text{drag}} = -m\bar{C}vv_x \hat{x} - m\bar{C}vv_y \hat{y} - m\bar{C}vv_z \hat{z}. \quad (31)$$

4.5 Turning Control Force

When control forces are used, it is assumed that some type of aerodynamic device that can cause a projectile to turn is present. Since the mechanism is assumed to be aerodynamic in nature, it is further assumed that the turning force will have a form that is similar to equation 28. Thus,

$$\vec{F}'_{\text{turn}} = \frac{1}{2}\rho C_{\text{turn}} \xi_{\text{turn}} v^2 \hat{y}'. \quad (32)$$

Two parameters are used to determine the magnitude of the turning control force. C_{turn} is projectile specific and is used to determine the maximum value of the turning control force given a particular air density and projectile speed. ξ_{turn} is situation specific and is meant to represent the proportion of the turning force being applied by the projectile, as well as the turning force direction (either left or right). Equation 33 gives the allowed values for ξ_{turn} . Note that the association between the sign of ξ_{turn} and the direction of the induced turn, left or right, is counterintuitive. A value of -1 indicates that the turning control force is at its maximum value and is causing the projectile to turn toward the $-\hat{y}'$ direction (i.e., *right*). A value of 1 indicates

that the control force is at its maximum value and is causing the projectile to turn toward the \hat{y}' direction (i.e., *left*). A value of 0 indicates that no turning force is being applied.

$$-1 \leq \xi_{turn} \leq 1. \quad (33)$$

It will be helpful to define a new value whose sole purpose is to simplify equations. Recall that γ is defined in equation 12.

$$\bar{C}_{turn} \equiv \frac{1}{2m} \rho C_{turn} \xi_{turn} \gamma. \quad (34)$$

Substituting equation 34 into equation 32 produces a simpler equation for the turning control force.

$$\vec{F}'_{turn} = m \bar{C}_{turn} \frac{v^2}{\gamma} \hat{y}'. \quad (35)$$

Next, inserting equations 35 and 17 into equation 10 produces an equation for the turning force in terms of the topocentric coordinate system.

$$\vec{F}_{turn} = -\bar{C}_{turn} m v v_y \hat{x} + \bar{C}_{turn} m v v_x \hat{y}. \quad (36)$$

4.6 Lifting Control Force

The lifting control force is treated in much the same manner as the turning control force. The major difference is that the lifting control force points in the \hat{z}' direction rather than the \hat{y}' direction. Thus,

$$\vec{F}_{lift} = \frac{1}{2} \rho C_{lift} \xi_{lift} v^2 \hat{z}', \quad (37)$$

where C_{lift} and ξ_{lift} are defined in a manner that is similar to C_{turn} and ξ_{turn} . With respect to direction, when ξ_{lift} is greater than 0, the lifting force has a component in the topocentric coordinate system that points in the \hat{z} direction. When ξ_{lift} is less than zero, the lifting force has a component in the topocentric coordinates system that points in the $-\hat{z}$ direction.

Just as with the turning control force, it will be helpful to define a new equation simplifying constant. Recall that γ is defined in equation 12.

$$\bar{C}_{lift} \equiv \frac{1}{2m} \rho C_{lift} \xi_{lift} \gamma. \quad (38)$$

Substituting equation 38 into equation 37 gives the lifting control force in a simpler form.

$$\vec{F}_{lift} = m \bar{C}_{lift} \frac{v^2}{\gamma} \hat{z}'. \quad (39)$$

Next, inserting equations 39 and 17 into equation 10 gives the lifting control force in terms of the topocentric coordinate system. Note that

$$\gamma^2 = \left(\frac{1}{\sqrt{1 - \frac{v_z^2}{v^2}}} \right)^2 = \frac{v^2}{v_x^2 + v_y^2} \Rightarrow \frac{v^2}{\gamma^2} = v_x^2 + v_y^2 \quad (40)$$

and

$$\vec{F}_{lift} = -\bar{C}_{lift} m v_x v_z \hat{x} - \bar{C}_{lift} m v_y v_z \hat{y} + \bar{C}_{lift} m (v_x^2 + v_y^2) \hat{z}. \quad (41)$$

4.7 Air Resistance From Control Forces

The act of applying a control force by a projectile will generally tend to increase the force due to air resistance that a projectile experiences. Equation 42 describes the additional drag caused by the application of a control force.

$$\vec{F}_{control\ drag} = -(R_{turn} F_{turn} + R_{lift} F_{lift}) \hat{x}. \quad (42)$$

The parameters R_{turn} and R_{lift} are used to represent the proportion of the control force that contributes to an increase in drag. Thus,

$$0 \leq R_{turn}, R_{lift} \leq 1. \quad (43)$$

From equations 1 and 21, it follows that

$$\vec{F}_{control\ drag} = -(R_{turn} F_{turn} + R_{lift} F_{lift}) \frac{v_x}{v} \hat{x} - (R_{turn} F_{turn} + R_{lift} F_{lift}) \frac{v_y}{v} \hat{y} - (R_{turn} F_{turn} + R_{lift} F_{lift}) \frac{v_z}{v} \hat{z}. \quad (44)$$

Just as with the turning and lifting control forces, it will be helpful to define a new equation simplifying constant.

$$\bar{C}_{control\ drag} \equiv \frac{1}{2m} \rho (R_{turn} C_{turn} |\xi_{turn}| + R_{lift} C_{lift} |\xi_{lift}|). \quad (45)$$

Using equations 32 and 37, equation 45 can be rewritten in terms of the magnitudes of the turning and lifting control forces.

$$\bar{C}_{control\ drag} = \frac{1}{m} (R_{turn} F_{turn} + R_{lift} F_{lift}) \frac{1}{v^2}. \quad (46)$$

Substituting equation 46 into equation 44 gives the final form of the force due to air resistance from the use of controls.

$$\vec{F}_{control_drag} = -m\bar{C}_{control_drag}vv_x\hat{x} + -m\bar{C}_{control_drag}vv_y\hat{y} + -m\bar{C}_{control_drag}v^2 \frac{v_z}{v}\hat{z}. \quad (47)$$

5. Equations of Motion

The equations of motion can be solved for in the standard manner by beginning with Newton's Second Law, which states that the sum of the forces acting on an object is equal to an object's mass multiplied by its acceleration.

$$\sum \vec{F} = m\vec{a}. \quad (48)$$

Solving equation 48 for acceleration and expanding the summation allows the spatial components of acceleration to be written in terms of the forces that were derived in section 4.

$$a_x = \frac{F_{grav,x}}{m} + \frac{F_{thrust,x}}{m} + \frac{F_{Coriolis,x}}{m} + \frac{F_{drag,x}}{m} + \frac{F_{turn,x}}{m} + \frac{F_{lift,x}}{m} + \frac{F_{control_drag,x}}{m}, \quad (49)$$

$$a_y = \frac{F_{grav,y}}{m} + \frac{F_{thrust,y}}{m} + \frac{F_{Coriolis,y}}{m} + \frac{F_{drag,y}}{m} + \frac{F_{turn,y}}{m} + \frac{F_{lift,y}}{m} + \frac{F_{control_drag,y}}{m}, \quad (50)$$

and

$$a_z = \frac{F_{grav,z}}{m} + \frac{F_{thrust,z}}{m} + \frac{F_{Coriolis,z}}{m} + \frac{F_{drag,z}}{m} + \frac{F_{turn,z}}{m} + \frac{F_{lift,z}}{m} + \frac{F_{control_drag,z}}{m}. \quad (51)$$

Finally, substituting the previously derived force equations 18, 24, 27, 31, 35, 41, and 47 into equations 49, 50, and 51 gives the final version of the equations of motion, which are presented in table 1.

Table 1. Equations of motion.

Gravity	Thrust	Coriolis	Drag	Turn	Lift	Control-Drag
$a_x = 0$	$+ \bar{T}v_x + 2\Omega(v_y \sin \Theta - v_z \cos \Theta) - \bar{C}vv_x$	$- \bar{C}_{turn}vv_y$	$- \bar{C}_{lift}v_xv_z$	$- \bar{C}_{drag}vv_x$		
$a_y = 0$	$+ \bar{T}v_y$	$- 2\Omega v_x \sin \Theta$	$- \bar{C}vv_y$	$+ \bar{C}_{turn}vv_x$	$- \bar{C}_{lift}v_yv_z$	$- \bar{C}_{drag}vv_y$
$a_z = -g$	$+ \bar{T}v_z$	$+ 2\Omega v_x \cos \Theta$	$- \bar{C}vv_z$	$+ 0$	$+ \bar{C}_{lift}(v_x^2 + v_y^2)$	$- \bar{C}_{drag}vv_z$

The equations of motion have been solved using a fourth-order Runge-Kutta method, which is presented in code form in appendix A.

6. C++ Code

The C++ code contained in appendices A and B has been specifically designed to be embedded into larger codes. The code has been designed to be as user friendly as possible. All available calculations are performed by setting and/or modifying 21 user-definable variables and calling four functions.

6.1 User-Definable Variables

The following is a list of user-definable variables. The name of the variable is listed on the left. If the name is followed by a symbol contained in parentheses, it is the name that is used in the equations contained in this report. If applicable, the required units of each parameter are contained in square brackets.

6.1.1 Projectile Parameters

diameter_	[m] The diameter of the projectile.
mass_ (m)	[kg] The mass of the projectile.
$C_{\text{turn}} (C_{\text{turn}})$	[m^2] The turning control coefficient.
$C_{\text{lift}} (C_{\text{lift}})$	[m^2] The lifting control coefficient.
$R_{\text{turn}} (R_{\text{turn}})$	[unitless] The drag scale factor for the turning control force.
$R_{\text{lift}} (R_{\text{lift}})$	[unitless] The drag scale factor for the lifting control force.
$\xi_{\text{turn}} (\xi_{\text{turn}})$	[unitless] The portion of the turning control force used.
$\xi_{\text{lift}} (\xi_{\text{lift}})$	[unitless] The portion of the lifting control force used.
thrust_mass_table_	This table is used only when rocket propulsion is present. If used, the table contains three columns. For each row, the first-column entry represents a time (in seconds), the second-column entry represents a thrust (in Newtons), and the third-column entry represents a mass (in kilograms). Time values must be in ascending order when moving down the table, with the first value typically being 0.0 s. Values in the thrust and mass columns represent the thrust and mass values that occur for the given projectile at the time indicated by the first column. For times that fall between the values stated in the first column, thrust and mass values are determined by performing a linear interpolation.

`drag_table_`

This table provides a piecewise function that can be used to determine the zero-yaw drag coefficient. The model is designed to accept standard zero-yaw drag coefficient tables such as those found in U.S. Department of Defense firing table manuals. (See FCI 155-AO-A for an example [8]). In these tables, the drag coefficients are given as polynomials in term of Mach number.

The last column of the table contains Mach numbers and is used to determine which row (i.e., which function) should be used to calculate the zero-yaw drag coefficient, where the Mach number given represents the maximum Mach number allowable for that row. The minimum Mach number allowable for a given row is given by the Mach number contained in the previous row, or zero if no previous row exists. All other columns represent the unitless coefficients of the polynomial describing the zero-yaw drag coefficient. Once the proper row is determined, the equation $C_D = \sum_{i=0}^{n-1} a_i M^i$ is used, where M is the projectile's current Mach number, n is the number of columns in the `drag_table_` variable, and a_i is the value of the polynomial coefficient given in the i th column of the table.

6.1.2 Environmental Parameters and Initial Conditions

`t0_`

[s] The initial time offset.

`x0_`

[m] The initial spatial offset in the \hat{x} direction.

`y0_`

[m] The initial spatial offset in the \hat{y} direction.

`z0_`

[m] The initial spatial offset in the \hat{z} direction.

`v0_`

[m/s] The initial speed of a projectile.

`elevation0_`

[radians] The angle between the initial velocity vector and the horizontal plane. If the initial velocity vector has a positive z component, then this angle will be positive.

`azimuth0_`

[radians] The angle between the projection of the initial-velocity vector onto the x - y plane and the x axis, measured counterclockwise.

`lat_(Θ)`

[radians] The latitude of the origin of the topocentric coordinate system.

`T0_`

[K] The temperature at the origin of the topocentric coordinate system.

`P0_`

[Pa] The pressure at the origin of the topocentric coordinate system.

6.1.3 Other

`delta_t_calc_` [s] The time step that is used in calculating the end state and the state at apogee.

6.2 State Vectors

State vectors are class members of the defined C++ container class *yVector*, which is presented in appendix B. The class is designed to function similar to the built-in C++ container class *vector<double>*. All state vectors contain 10 elements and are used to represent the state of the projectile in the topocentric coordinate system. Table 2 provides a cross-referenced list between a state vector's element numbers and the values contained in a state vector.

Table 2. Description of the elements contained in a state vector.

Element No.	Description	Units
0	time	s
1	x	m
2	y	m
3	z	m
4	vx	m/s
5	vy	m/s
6	vz	m/s
7	ax	m/s^2
8	ay	m/s^2
9	az	m/s^2

6.3 Functions

Four functions are available for calculating various state vectors. Three accept state vectors as arguments, all four return state vectors. (Refer to section 6.2 for a description of state vectors.)

6.3.1 Initial()

This function calculates the initial state of a projectile based solely on user-defined parameters.

6.3.2 Next()

Given the current state of a projectile, this function calculates the state of the projectile at some given time after the current time.

6.3.3 Apogee()

Given the current state of a projectile, this function calculates the state of the projectile at apogee. Note that the user-defined variable `delta_t_calc_` is used to determine the time step between iterations.

6.3.4 End()

Given the current state of a projectile, this function calculates the state of the projectile at its end state. The end state is defined to be the state of the projectile when it returns to ground level (i.e., when $z = 0$ and $v_z < 0$). Note that the user-defined variable `delta_t_calc_` is used to determine the time step between iterations.

6.4 Using the Code

Section A.1 of appendix A presents a simple example of how the projectile model can be included in custom-written C++ code. Projectile parameters, environmental parameters, and initial conditions are easily defined by accessing class-member variables. Four simple functions provide flexibility for the model. All four functions return a state vector that describes the position, velocity, and acceleration of a projectile at a given time.

//*****
***          ATMOSPHERE CLASS
**      version 1.10 (01-23-2011)
**          -Rob Yager
***      ****
*****
```

The functions contained in this class can be used to calculate temperature, pressure, density, and speed of sound for specified altitudes. This code is an implementation of the model developed in "U.S. Standard Atmosphere, 1976."

Height Limits:

Do not use the atmospheric functions contained in this class for altitudes above 86,000 m. Also, the atmospheric model used to create the functions in this class is not guaranteed to be accurate below 5000 meters below sea level.

Temperature Function:

The temperature that is calculated is actually the molecular-scale temperature (rather than the kinetic temperature). However, up to about 80,000 m the two are identical. From 80,000 m to 86,000 m the difference between the two is trivial. The largest difference occurs at 86,000 m and is about 0.008%. See page 9 of "U.S. Standard Atmosphere, 1976" for more details.
